# Outline

- Motivation
- Why pacing could be more bursty?
- The impact of network variabilities on the behavior of TCP clocking schemes
- Conclusion

# TCP Clocking Schemes

- Self-clocking (a.k.a. ack-clocking)
  - ACKs “self-clock” the data to the rate of the bottleneck link
- Pacing
  - resembles to a rate control mechanism but preserves the concept of window control
  - a common implementation: release a window of packets **evenly** within each round-trip time
- In intuition, pacing will result in more smooth traffic, and smooth traffic will lead to better performance, however, ...

# Motivation

- Aggarwal, Savage, Anderson found pacing often results in lower throughput and higher latency.
- We are motivated to evaluate ack-clocking and pacing schemes with more fundamental behavioral analysis, especially on the aspect of **traffic burstiness**.

# Our main results

- Pacing traffic could be **more bursty** than ack-clocking traffic.
- The comparative traffic burstiness of TCP clocking schemes are largely affected by **network path properties**
  - whether the round-trip times (RTT) are the same
  - the number of flows
- Pacing is generally less bursty than ack-clocking with **realistic settings**, i.e., heterogeneous RTT flows.

# Why pacing could be more bursty?

- Intuitively, pacing should be no more bursty than ack-clocking.
- We shall illustrate why the phenomenon could happen by behavioral models.

# Behavioral models – equal window size

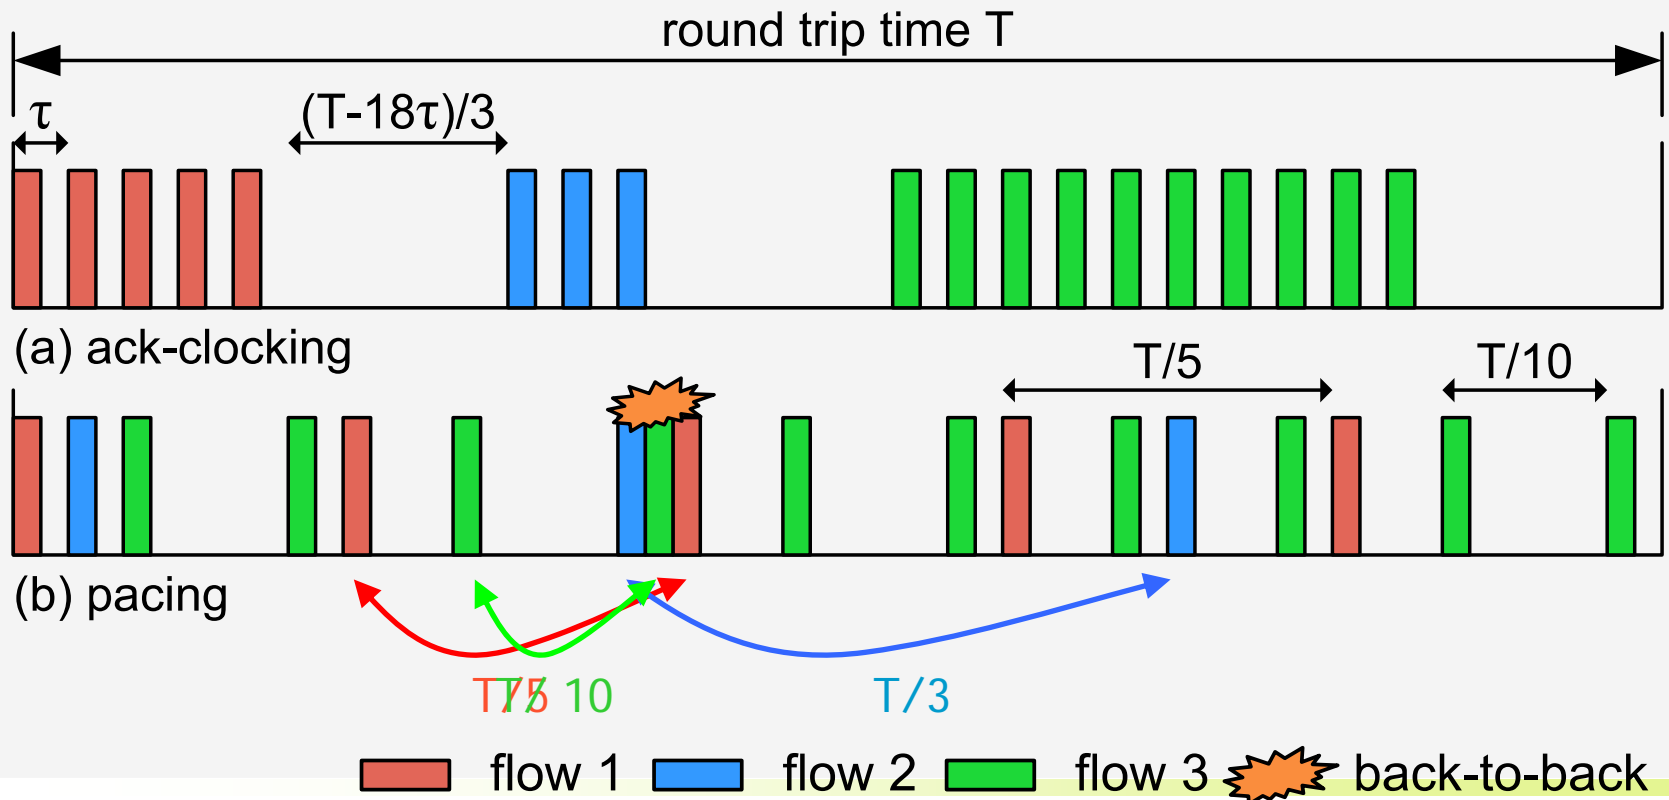

- Assumption: 3 flows, the same RTT, equal window size = 6

- $\tau$ : bottleneck delay packet trains are equally spaced in a RTT

# Behavioral models – different window size

- Assumption: 3 flows, the same RTT, different windows size = 5, 3, 10, respectively.

# The effect of window un-synchronization

- Generate packet arrival sequences by the behavioral models
  - $T = 100 \text{ ms}$ ,  $\tau = 0.1 \text{ ms}$ , 3 flows
  - compare two cases
    - synchronized windows: 30, 30, 30
    - un-synchronized windows: 20, 30, 40
- Observe traffic burstiness based on the wavelet-based MultiResolution Analysis (MRA) for the synthesized traffic.

# The energy plot

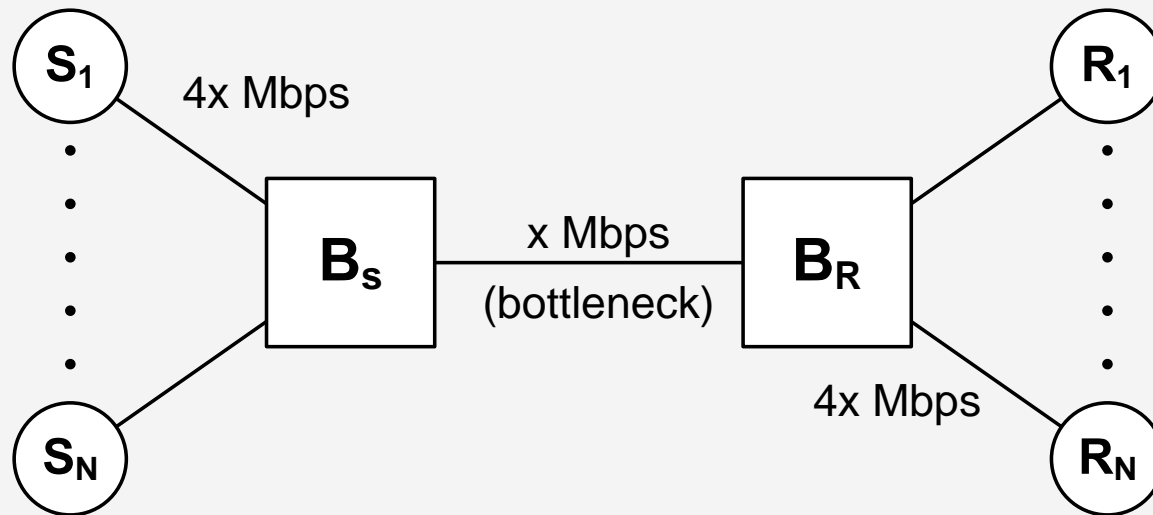

- Ack-clocking nearly remains its burstiness
- Pacing become more bursty
- The effect can be amplified by more flows (show later)

# Validation and Simulations

- Observation: window un-synchronization can raise burstiness of pacing traffic.
- We conduct network simulations to:
  - validate the observation
  - examine the impact of flow multiplexing
  - examine the impacts of other variabilities

# Simulation Setup

- the network simulator is *ns-2*
- 1--50 flows, RTT are fixed to 100 ms
- network topology

# The Effect of Multiplexing – Ack-clocking

- more bursty in small scales (still less bursty than Poisson)
- much less bursty in large scales

# The Effect of Multiplexing – Pacing

- burstiness raises in all sub-RTT time scales
- due to the effect of window un-synchronization.

# The Effect of Multiplexing – A Comparison

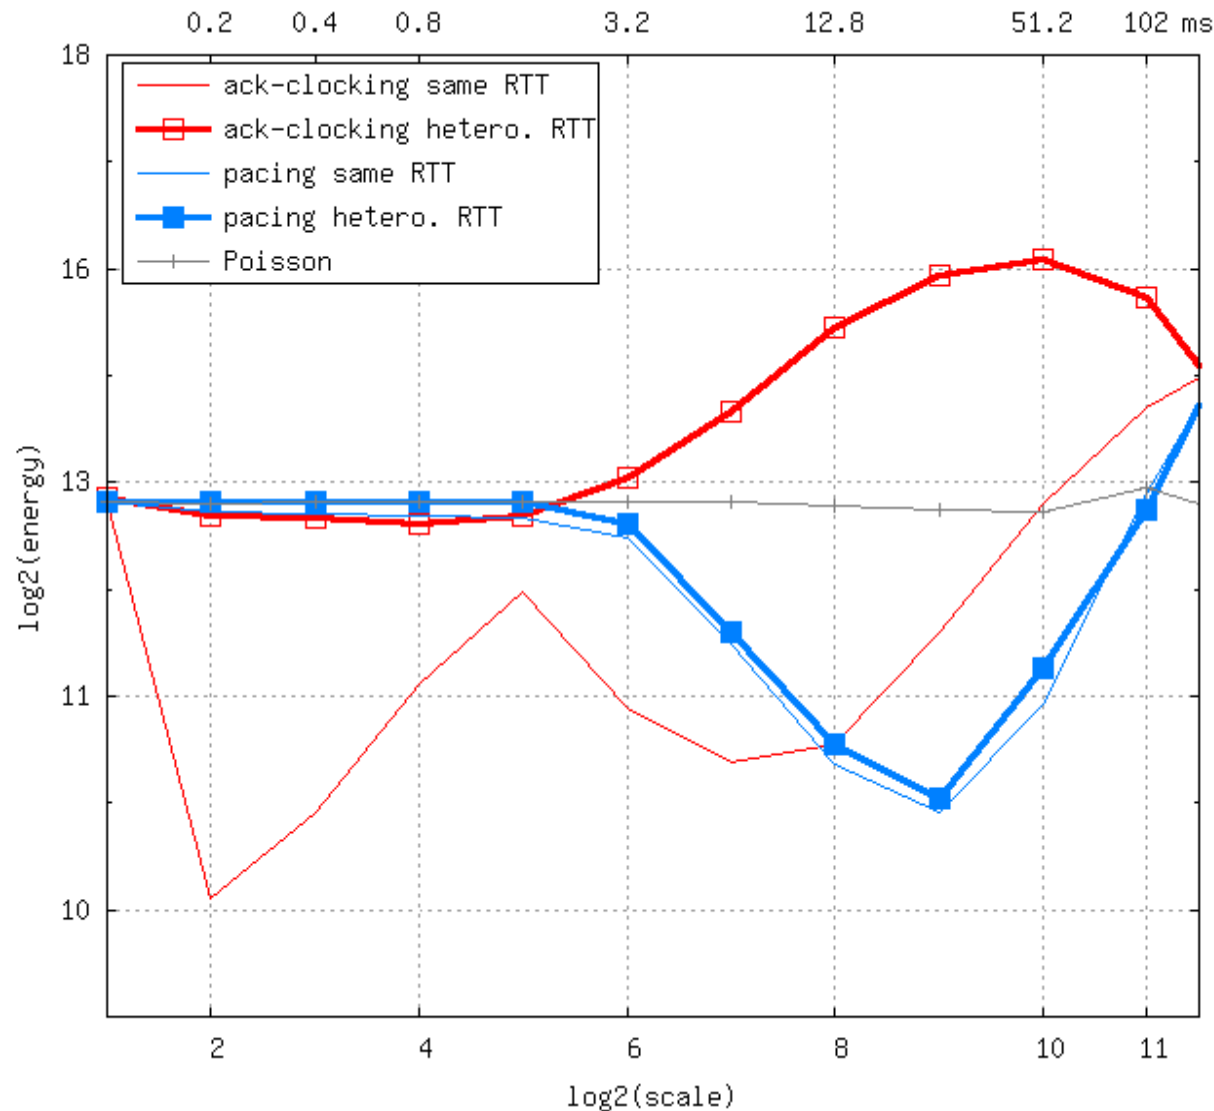

- 50 flows  $\Rightarrow$  pacing is **more bursty** in most of sub-RTT time scales
- the comparative burstiness of two schemes are **very different** with and without flow multiplexing

# Examine the effect of RTT heterogeneity

- The simulation setup is almost the same except:
  - fixed to 50 flows
  - RTTs are drawn from an uniform distribution over (100 ms, 300 ms)

# The Effect of RTT Heterogeneity

- Ack-clocking is much **more bursty**
  - mismatch of round trip times
  - ack-solicited pkts are no longer spaced by  $\tau$
- Pacing is **unaffected**
  - RTT/window is already randomized by unsynchronized windows

# More Network Variabilities

- Simulations with additional factors:
  - multi-hop, two-way traffic, cross-traffic, and their combinations

<i>ID</i>	<i>Topology</i>	<i>RTT Heter.</i>	<i>Two-Way Traffic</i>	<i>Cross Traffic</i>
<i>Fixed</i>	Dumbbell	-	-	-
<i>VarRTT</i>	Dumbbell	✓	-	-
<i>TwoWay</i>	Dumbbell	✓	✓	-
<i>Cross</i>	Dumbbell	✓	-	✓
<i>Real</i>	Parking-lot	✓	✓	✓

# Network Variabilities on Ack-clocking

- The heterogeneity in flows RTT is a deciding factor.

# Network Variabilities on Pacing

- None of variabilities significantly affect pacing's behavior
  - As long as RTTs are heterogeneous:
    - Ack-cloking is no less bursty than Poisson
    - Pacing is no more bursty than Poisson
- ⇒ Pacing is less bursty

# Conclusion

- Provided **physical explanation** for ‘why pacing could be more bursty than ack-clocking’
- Comparative burstiness of the TCP clocking schemes are **network condition dependent**, especially RTT heterogeneity and flow multiplexing.
- It's critical to include **sufficient variabilities** in performance evaluation of TCP based protocols.

**Thank You!**
